The TWEAK Receptor Fn14 Is an Src-Inducible Protein and a Positive Regulator of Src-Driven Cell Invasion

Emily Cheng, Timothy G. Whitsett, Nhan L. Tran, and Jeffrey A. Winkles

Abstract

The TNF receptor superfamily member Fn14 (TNFRSF12A) is the sole signaling receptor for the proinflammatory cytokine TWEAK (TNFSF12). TWEAK:Fn14 engagement stimulates multiple signal transduction pathways, including the NF-kB pathway, and this triggers important cellular processes (e.g., growth, differentiation, migration, and invasion). The TWEAK–Fn14 axis is thought to be a major physiologic mediator of tissue repair after acute injury. Various studies have revealed that Fn14 is highly expressed in many solid tumor types, and that Fn14 signaling may play a role in tumor growth and metastasis. Previously, it was shown that Fn14 levels are frequently elevated in non–small cell lung cancer (NSCLC) tumors and cell lines that exhibit constitutive EGFR phosphorylation (activation). Furthermore, elevated Fn14 levels increased NSCLC cell invasion in vitro and lung metastatic tumor colonization in vivo.

Introduction

Lung cancer is the most commonly diagnosed cancer and the leading cause of cancer-related deaths worldwide; in the United States, it is predicted that approximately 224,000 people will be diagnosed with lung cancer and approximately 159,000 patients will die from this disease in 2014 (1). Despite extensive basic and clinical research efforts, the 5-year survival rate for all patients with lung cancer is approximately 17% (1). Non–small cell lung cancer (NSCLC) is the most common lung cancer histologic subtype (~85% of all lung cancers), and these tumors can be further divided into adenocarcinoma (50% of all NSCLCs), squamous cell carcinoma or large-cell carcinoma (2). Treatment options for patients with NSCLC depend on disease stage and include surgery for localized tumors and radiotherapy and/or platinum-based chemotherapy for advanced or recurrent metastatic disease (3). Our therapeutic options for certain patients with NSCLC have recently expanded because of the discovery that some NSCLC tumors harbor specific gene mutations that drive cancer cell growth and survival (4). The two most frequently mutated genes in patients with NSCLC are KRAS (~25% of lung adenocarcinomas; ref. 5) and EGFR (~20% of lung adenocarcinomas; refs. 6–8). Although targeted therapeutic agents have been developed for the EGFR-mutant patient subgroup [e.g., the tyrosine kinase inhibitor (TKI) erlotinib], drug resistance is a major clinical problem (6–8). There are no FDA-approved targeted drugs for the great majority of patients with NSCLC; therefore, studies focused on the identification of new molecules that regulate NSCLC cell biology, and the development of new therapeutics targeting these molecules, are of critical importance.

TNF-like weak inducer of apoptosis (TWEAK; TNFSF12), a member of the TNF superfamily of cytokines, acts on cells via binding to a single TNF receptor superfamily member named FGF-inducible 14 (Fn14; TNFRSF12A; refs. 9, 10). TWEAK:Fn14 engagement activates a number of intracellular signal transduction cascades, and this can result in either increased cell proliferation, survival, migration, differentiation or death, depending on the cellular context (9, 10). Studies using TWEAK-deficient mice, Fn14-deficient mice, and/or TWEAK-neutralizing biologics have revealed that TWEAK–Fn14 signaling after acute tissue injury is critical for efficient wound repair and that chronic, dysregulated Fn14 signaling may play an important role in the pathophysiology of several prominent human diseases, including cancer (9, 10). Both TWEAK and Fn14 expression have been detected in primary tumors and tumor metastases and Fn14 gene expression in particular is frequently elevated in primary tumor tissue compared with matched adjacent normal tissue or normal tissues.

from nondiseased donors (10–19). In addition, there are reports indicating that the TWEAK–Fn14 axis may play an important role in regulating various aspects of tumor growth and metastasis, including cancer cell proliferation (15, 16), chemotherapeutic drug sensitivity (20), and migratory/invasive capacity (11, 12, 14, 15, 17, 21–23). In consideration of these findings, a number of TWEAK- or Fn14-targeted agents are presently in preclinical development or in clinical trials for cancer therapy (10).

Previously, we showed that Fn14 was overexpressed in NSCLC tumors (17), and that high Fn14 levels were most frequently found in those tumors that exhibited strong p-EGFR (Y-1068) antibody immunostaining, an indicator of constitutive EGFR activation (17). We also reported that the HCC827 NSCLC cell line that harbors an EGFR-activating mutation (AE746-A750) has relatively high levels of Fn14 protein expression, and that erlotinib treatment of these cells significantly reduced Fn14 levels, indicating that EGFR signaling was in fact inducing Fn14 expression in these cells.

In this study, we investigated which EGFR-triggered downstream intracellular signaling pathways were driving Fn14 expression in HCC827 cells. We found that although EGFR activation of multiple signaling pathways contributes to the overall level of Fn14 expression, the activation of Src, a non–receptor tyrosine kinase that is functionally integrated into various signaling cascades and causally linked to tumor growth and metastasis (24, 25), was a particularly critical signaling event. The importance of the Src signaling node for EGFR-driven Fn14 expression was initially discovered using the Src family kinase (SKF) inhibitor dasatinib, and then confirmed using an RNAi approach. In addition, we show here that Fn14 expression is significantly higher in an NIH 3T3 cell line engineered to express the constitutively active v-Src oncoprotein in comparison with control NIH 3T3 cells, and that the NIH 3T3/v-Src cells require Fn14 expression for full invasive capacity.

Materials and Methods
Cell culture and treatments
Human NSCLC cell lines A549, H1975, and HCC2279 (ATCC) were maintained in RPMI-1640 (Sigma-Aldrich) supplemented with 10% FBS, 2 mmol/L l-glutamine, and 1% penicillin-streptomycin (both from CellGro). HCC827 cells (ATCC) were maintained in RPMI-1640 supplemented with 5% FBS, 2 mmol/L l-glutamine, and 1% penicillin-streptomycin. The four cell lines listed above were validated by short tandem repeat DNA fingerprinting using the Promega PowerPlex 16HS System at the University of Arizona Genetics Core Facility in October 2014. NIH 3T3 cells (ATCC) were maintained in DMEM (CellGro) supplemented with 10% FBS, 2 mmol/L l-glutamine, 0.15% sodium bicarbonate (CellGro), and 1% penicillin-streptomycin. The NIH 3T3/v-Src cell line was provided by Dr. Steven Zhan (University of Maryland School of Medicine, Baltimore, MD) and maintained in DMEM supplemented with 10% FBS, 2 mmol/L l-glutamine, 0.15% sodium bicarbonate, and 1% penicillin-streptomycin. All cells were maintained at 37°C in 5% CO2.

Cells were serum-starved overnight in media containing 0.5% FBS unless otherwise indicated and then treated with either DMSO vehicle (Sigma-Aldrich) or the indicated concentrations of erlotinib (BioVision), MK-2206 (BioVision), EGF (R&D Systems), dasatinib (Cell Signaling Technology), U0126 (Cell Signaling Technology), BAY 11-7082 (EMD Millipore), or STAT3 inhibitor VIII (5,15-DPP; Santa Cruz Biotechnology).

Western blot analysis
Cells were harvested by scraping and lysed in 20 mmol/L HEPES, 150 mmol/L NaCl, 1.5 mmol/L MgCl2, 10% glycerol, and 1% Triton X-100 supplemented with a protease inhibitor cocktail (Sigma-Aldrich) and two phosphatase inhibitor cocktails (Calbiochem). The protein concentration of each lysate was determined by BCA protein assay (Pierce Protein Biology). Equal amounts of protein were subjected to SDS-PAGE (Life Technologies) and electrotransferred to polyvinylidene difluoride membranes (Millipore). Membranes were blocked in either 5% BSA in Tris-Buffered Saline with 0.05% Tween (TBST) or 5% non-fat dry milk in TBST buffer, and then sequentially incubated with the appropriate primary antibody and horseradish peroxidase–conjugated secondary antibody (Cell Signaling Technology). The membranes were washed in TBST, and then immunoreactive proteins were detected using the Amersham Enhanced Chemiluminescence Plus Kit (GE Healthcare) according to the manufacturer’s instructions. The following primary antibodies were used: Fn14, p-EGFR (Y-1068), p-EGFR (Y-845), EGFR, pan p-Src (Y-416), Src, Lyn, Lck, GAPDH, p-ERK (T-202/Y-204), ERK, p-JNK (T-183/Y-185), JNK, p-Akt (S-473), Akt, p-STAT3 (Y-705), STAT3, p100/p52 (all from Cell Signaling Technology), and tubulin (Sigma-Aldrich). Densitometric analysis was conducted using ImageJ software and all Fn14 or Src expression values were normalized to GAPDH or tubulin values.

RNA isolation and quantitative real-time RT-PCR assays
Total cellular RNA was extracted using the RNeasy Kit (Qiagen) according to the manufacturer’s instructions and 1 μg of RNA was converted to cDNA using the ProtoScript AMV LongAmp RT-PCR Kit (New England Biolabs). Fn14, GAPDH and ribosomal protein L13a mRNA levels were quantified as previously described (21).

siRNA transfections
Cells were plated and allowed to attach for 5 hours, and then transfected with transfection reagent alone (no siRNA), luciferase siRNA, Src siRNAs #7 or #10 targeted to the human Src transcript, or Fn14 siRNAs #1 and #4 targeted to the murine Fn14 transcript at a final concentration of 20 nmol/L using RNAiMax transfection reagent (Life Technologies) according to the manufacturer’s instructions. All siRNAs were purchased from Qiagen. Cells were harvested at 48 (Fn14 siRNA) or 72 (Src siRNA) hours posttransfection, lysed and Western blot analysis conducted as described above.

Cell invasion assays
Cells were harvested, resuspended in media containing 0.5% serum, and plated in triplicate in Boyden chambers precoated with growth factor–reduced Matrigel (BD Biosciences). The chambers were then placed in 24-well plates (Corning) with growth media containing 10% FBS as a chemoattractant. Cells were allowed to invade for 20 hours, and then fixed and stained as previously described (17). Cells from five randomly chosen fields were counted at ×20 magnification under a light microscope and summed to calculate total number of cells invaded.

Statistical analysis
Real-time RT-PCR and cell invasion assay results are presented as mean ± SEM and the two-sample Student t test was used to
the Ras activation, the stimulation of various interrelated signaling cascades, including the Ras–Raf–MEK–ERK and PI3K–Akt pathways, which are generally associated with cell proliferation and survival (7, 8). EGFR activation also stimulates the STAT (8, 26) and NF-κB (27) pathways, which trigger the activation of latent, cytoplasmic transcriptional regulators that modulate gene expression. In addition, both ligand-activated, wild-type EGFR (28) and the gain-of-function EGFR mutants that are expressed in a subset of NSCLC tumors (29) can physically associate with c-Src, leading to Y-416 autophosphorylation, kinase activation, and downstream cellular responses (28–31). We investigated whether one or more of these signaling pathways were critical for EGFR-driven Fn14 expression by treating HCC827 cells with either erlotinib (EGFR inhibitor; a positive control for complete Fn14 downregulation; ref. 17), U0126 (MEK inhibitor), MK-2206 (Akt inhibitor), BAY-11-7082 (IKK inhibitor), dasatinib (Src inhibitor), or 5,15-DPP (STAT3 inhibitor) for 8 hours. Cell lysates were prepared and Western blot analysis was performed. All of the downstream pathway pharmacologic inhibitors decreased Fn14 levels, but dasatinib had the most potent inhibitory effect under our experimental conditions (i.e., drug doses and treatment time; Fig. 1A).

Although dasatinib is largely selective for BCR–ABL and SFK members at low doses, it can inhibit many other tyrosine kinases (32–34), including EGFR (35), at higher doses. We chose our dasatinib concentration (30 nmol/L) in consideration of a prior report using HCC827 cells indicating that this dosage should effectively inhibit Src signaling but not EGFR signaling (35). To confirm that this was indeed the case, HCC827 cells were treated with erlotinib or dasatinib for 8 hours, cell lysates were prepared, and Western blot analysis was conducted. Src activation was assessed using a pan p-Src antibody that was raised against a synthetic phosphopeptide corresponding to residues surrounding Y-416 of human Src. This antibody may cross-react with other SFK members when phosphorylated at an equivalent site. EGFR activation was assessed using an antibody that detects phosphorylation at Y-1068, one of the major EGFR autophosphorylation sites. We also examined the phosphorylation status of EGFR residue Y-843. Phosphorylation on this tyrosine can be mediated by Src (28, 29, 36), Brk/PTK6 (37), and in some cases, by EGFR itself (38). Constitutive EGFR and Src phosphorylation was noted in HCC827 cells, consistent with previous reports (Fig. 1B; refs. 17, 30, 31, 35, 39). Cells treated with erlotinib for 8 hours had reduced p-EGFR (Y-1068, Y-845) but not reduced p-Src levels, consistent with a prior report (40). However, when cells were treated with dasatinib for 24 hours, p-Src levels were reduced, indicating a linkage between EGFR kinase activity and Src phosphorylation (Supplementary Fig. S1). Cells treated with dasatinib had significantly reduced p-Src levels, but p-EGFR (Y-1068 and Y-845) levels were unaffected (Fig. 1B). Taken together, these results indicate that at the drug dosages and time point used for this experiment, (i) EGFR tyrosine kinase activity is responsible for both Y-1068 and Y-845 phosphorylation in HCC827 cells, and (ii) the dasatinib-mediated reduction in Fn14 expression in HCC827 cells is not due to inhibition of EGFR tyrosine kinase activity.

Dasatinib treatment of HCC827 cells decreases both Fn14 protein and mRNA expression levels

We next examined the effect of dasatinib on Fn14 protein expression in more detail by conducting dose–response and time-course experiments. First, HCC827 cells were treated with varying concentrations of dasatinib for 8 hours, cell lysates were prepared, and Western blot analysis was performed. Fn14 levels decreased in a dose-dependent manner, with the greatest effect detected using 100 nmol/L dasatinib (Fig. 2A). Next, we treated HCC827 cells with 30 nmol/L dasatinib for increasing amounts of...
Dasatinib also inhibited Fn14 levels in a time-dependent manner, with the greatest effect seen at 12 hours post-drug addition (Fig. 2B).

We then determined whether dasatinib treatment of HCC827 cells reduced Fn14 mRNA levels. For this analysis, cells were treated with 30 nmol/L dasatinib for 2, 4, or 8 hours, cells were harvested, RNA was isolated, and Fn14 and GAPDH mRNA levels were quantitated by real-time RT-PCR. We found that Fn14 mRNA levels decreased within 2 hours of dasatinib treatment, with maximal reduction noted at 8 hours, the last time point examined (Fig. 2C). This finding indicates that the dasatinib-mediated reduction in Fn14 protein levels in HCC827 cells is likely due, at least in part, to a decrease in Fn14 mRNA levels.

Figure 2.
Effect of dasatinib treatment on Fn14 protein and mRNA levels in HCC827 cells. A, HCC827 cells were serum-starved overnight and then treated with either vehicle or the indicated concentrations of dasatinib for 8 hours. Cells were harvested and Fn14 and GAPDH levels were analyzed by Western blotting. B, cells were either vehicle treated or treated with dasatinib (30 nmol/L) for the indicated time periods. Western blot analysis was conducted as described in A. C, cells were serum-starved overnight and then treated with either vehicle or dasatinib (30 nmol/L) for the indicated times. Cells were harvested, RNA was isolated, and Fn14 and GAPDH mRNA levels were measured using quantitative real-time PCR. Fn14 mRNA expression levels were normalized to GAPDH expression levels and presented as fold expression relative to vehicle control. The values shown are mean ± SEM of triplicate wells. Significance was measured by the Student t test; *, P < 0.05; **, P < 0.001.

Figure 3.
Effect of dasatinib treatment on Fn14 protein levels in EGFR-mutant HCC2279 cells, EGFR-mutant H1975 cells, and EGF-stimulated, EGFR wild-type A549 cells also decreases Fn14 protein levels.

Dasatinib treatment of EGFR-mutant HCC2279 cells, EGFR-mutant H1975 cells, and EGF-stimulated, EGFR wild-type A549 cells also decreases Fn14 protein levels.

To assess whether the inhibitory effect of dasatinib on Fn14 gene expression occurred in other NSCLC cell lines that harbor an activating EGFR mutation, we treated HCC2279 and H1975 cells, which are known to express constitutively active EGFR (17) and Src (30, 35), with 30 nmol/L dasatinib for 8 hours. We found that dasatinib was also a potent inhibitor of p-Src levels and Fn14 protein levels in these two cell lines (Fig. 3A).

Figure 3.
Effect of dasatinib treatment on Fn14 protein levels in EGFR-mutant HCC2279 and H1975 cells and EGF-stimulated, EGFR wild-type A549 cells. A, HCC2279 and H1975 cells were serum-starved overnight and then either left untreated or treated with EGF (50 ng/mL) alone, EGF and drug vehicle, or EGF and dasatinib (30 nmol/L) for the indicated time periods. Cells were harvested and Fn14, p-Src, Src, p-EGFR, EGFR, and GAPDH levels were analyzed by Western blotting.
We reported previously that EGF stimulation of serum-starved A549 NSCLC cells transiently increases Fn14 protein levels (17). These cells do not contain an EGFR-activating mutation and do not exhibit constitutive Src signaling (17, 35). Therefore, we selected these cells for testing whether EGF-driven Fn14 expression could also be mediated by Src activity. Cells were either left untreated or treated with EGF in the absence or presence of vehicle (DMSO) or dasatinib for 4 or 12 hours. Cell lysates were prepared and Western blot analysis was conducted. We found that EGF treatment of A549 cells stimulated Fn14 expression by approximately 2.5-fold and approximately 1.4-fold at the 4- and 12-hour time points, respectively (Fig. 3B). EGF also increased p-Src and p-EGFR (Y-1068, Y-845) levels. EGF exposure reduced total EGFR levels, consistent with previous studies showing that EGF:EGFR engagement promotes EGFR internalization, ubiquitination, and degradation via the lysosomal pathway (41, 42). The EGF-mediated p-Src and p-EGFR (Y-845) increase, but not the p-EGFR (Y-1068) increase, was inhibited by dasatinib cotreatment. Dasatinib treatment had no significant effect on EGF-stimulated Fn14 expression at the 4-hour time point, but completely inhibited Fn14 expression at the 12-hour time point, indicating that Src activation following EGF:EGFR engagement also contributes to Fn14 gene regulation.

Fn14 protein levels are decreased in Src-depleted HCC827 cells

As mentioned above, dasatinib likely inhibits all SFK members at the dosage we have used here and could potentially reduce the activity of other structurally similar tyrosine kinases as well (32, 34). A prior study examining global tyrosine kinase activation in cancer cell lines found that HCC827 cells express tyrosine phosphorylated Src, Lyn, and Lck but not Blk, Fgr, Fyn, nor Hck (39). We hypothesized that Src may be the main SFK member contributing to EGF-driven Fn14 expression in HCC827 cells because it has been previously demonstrated to both be physically associated with EGFR in NSCLC cells with activating EGFR mutations (29) and constitutively active in these cells (39). To test this hypothesis, cells were either left untransfected or transfected with luciferase (Luc) siRNA or two different Src siRNAs. Cells were harvested 72 hours later and Western blot analysis was conducted. Src expression was increased slightly in the Luc siRNA–transfected cells (by ~2%), but it was reduced by approximately 48% and 65% in the Src siRNA #7- or Src siRNA #10-transfected cells, respectively (as compared with the untransfected cells; Fig. 4). The amount of intracellular p-Src protein was also reduced following Src siRNA addition. Neither Luc siRNA nor Src siRNA treatment had an effect on expression of the related SFKs Lyn or Lck. We found that Luc siRNA treatment increased Fn14 protein levels (by ~24%) whereas Src siRNA #7 or Src siRNA #10 treatment reduced Fn14 protein levels by approximately 72% and 93%, respectively, as compared with the untransfected cells, indicating that full Src function is required for EGF-driven Fn14 expression.

Constitutive Src activity in engineered NIH 3T3 cells increases both Fn14 expression and invasive activity

To test whether constitutive Src signaling could upregulate Fn14 expression in other cell lines besides EGFR-activated NSCLC cells, we compared Fn14 levels in control and v-Src–transformed NIH 3T3 cells by Western blot analysis. The NIH 3T3/v-Src cells exhibited constitutive Src phosphorylation (Fig. 5A), as expected, and numerous other signaling pathways were also activated in these cells, including the ERK, JNK, Akt, and STAT3 pathways (Supplementary Fig. S2), consistent with previous reports (43, 44). Furthermore, v-Src expression in NIH 3T3 cells stimulated NF-κB (p100/p52) processing, which is indicative of alternative NF-κB pathway activation (Supplementary Fig. S2). We found that the NIH 3T3/v-Src cells expressed significantly more Fn14 protein than the control NIH 3T3 cells (~4.5-fold increase; Fig. 5A), which supports our NSCLC cell data, indicating that Fn14 is a Src-inducible gene. We should note here that in some cell lines, including these NIH 3T3/v-Src cells, two Fn14 isoforms are detected by Western blot analysis. The higher molecular weight form is full-length Fn14, whereas the lower molecular weight form is believed to be a either an Fn14 mRNA splice variant product or a proteolytically cleaved isoform of full-length Fn14 missing most of the extracellular domain (45). To determine whether v-Src expression also increased Fn14 mRNA levels, control and v-Src expressing NIH 3T3 cells were harvested, RNA was isolated, and Fn14 and ribosomal protein L13a mRNA levels were quantitated by real-time RT-PCR. We found that Fn14 mRNA levels were increased in the NIH 3T3/v-Src cells (Fig. 5B).

Figure 4. Effect of Src depletion on Fn14 protein levels in HCC827 cells. HCC827 cells were either left untransfected or transfected with the indicated siRNAs (20 nmol/L). Cells were harvested 72 hours posttransfection and Fn14, Src, p-Src, Lyn, Lck, and GAPDH levels were analyzed by Western blotting.

Constitutive Src activity in engineered NIH 3T3 cells increases both Fn14 expression and invasive activity

To test whether constitutive Src signaling could upregulate Fn14 expression in other cell lines besides EGFR-activated NSCLC cells, we compared Fn14 levels in control and v-Src–transformed NIH 3T3 cells by Western blot analysis. The NIH 3T3/v-Src cells exhibited constitutive Src phosphorylation (Fig. 5A), as expected, and numerous other signaling pathways were also activated in these cells, including the ERK, JNK, Akt, and STAT3 pathways (Supplementary Fig. S2), consistent with previous reports (43, 44). Furthermore, v-Src expression in NIH 3T3 cells stimulated NF-κB (p100/p52) processing, which is indicative of alternative NF-κB pathway activation (Supplementary Fig. S2). We found that the NIH 3T3/v-Src cells expressed significantly more Fn14 protein than the control NIH 3T3 cells (~4.5-fold increase; Fig. 5A), which supports our NSCLC cell data, indicating that Fn14 is a Src-inducible gene. We should note here that in some cell lines, including these NIH 3T3/v-Src cells, two Fn14 isoforms are detected by Western blot analysis. The higher molecular weight form is full-length Fn14, whereas the lower molecular weight form is believed to be a either an Fn14 mRNA splice variant product or a proteolytically cleaved isoform of full-length Fn14 missing most of the extracellular domain (45). To determine whether v-Src expression also increased Fn14 mRNA levels, control and v-Src expressing NIH 3T3 cells were harvested, RNA was isolated, and Fn14 and ribosomal protein L13a mRNA levels were quantitated by real-time RT-PCR. We found that Fn14 mRNA levels were increased in the NIH 3T3/v-Src cells (Fig. 5B).

SFKs, via their effects on gene expression, cytoskeletal reorganization, and cellular adhesion, are major intracellular mediators of tumor cell migration and invasion (24, 25, 46, 47). Therefore, we next compared the basal invasive activity of control NIH 3T3 cells and the NIH 3T3/v-Src cells using modified Boyden chambers coated with basement membrane extract (Matrigel). We found that the NIH 3T3/v-Src cells invaded approximately 3.5-fold more than the control NIH 3T3 cells (Fig. 5C), consistent with an earlier report (43).
NIH 3T3/v-Src cell invasive activity is decreased by Fn14 depletion

Several studies have demonstrated that experimental manipulation of Fn14 levels in cancer cells using either an RNAi or ectopic Fn14 overexpression strategy can modulate the basal invasive activity of these cells (11, 12, 14, 15, 17, 21). However, there are no reports indicating that Fn14 can act as a downstream effector of Src-driven invasiveness. To test whether this was the case, we used the Fn14-positive, highly invasive NIH 3T3/v-Src cells described above and an RNAi approach to investigate whether Fn14 expression was important for Src-driven cell invasion. Cells were either left untransfected or transfected with Luc siRNA or two different Fn14 siRNAs, harvested 48 hours later, and Western blot analysis was conducted. Fn14 expression was increased in the Luc siRNA–transfected cells by approximately 10%, but reduced in the Fn14 siRNA #1- or #4-transfected cells by approximately 88% and 57%, respectively (as compared with the untransfected cells; Fig. 6A). Neither Luc siRNA nor Fn14 siRNA treatment had an effect on p-Src or Src expression levels. A portion of the same cells harvested for Western blot analysis was plated into Matrigel invasion chambers to determine the effect of Fn14 depletion on NIH 3T3/v-Src cell invasive activity. There was no statistically significant difference in the invasive capacity of the untransfected cells as compared with the Luc siRNA–transfected cells (Fig. 6B). However, Fn14 depletion using siRNA #1 or #4 reduced the invasive capacity of the NIH 3T3/v-Src cells by approximately 40% and 27%, respectively (as compared with the untransfected cells), demonstrating that Fn14 expression is required for maximal Src-mediated cellular invasiveness.

In summary, we report here that EGFR-driven Fn14 expression in NSCLC cells, resulting from either ligand (EGF) engagement or the presence of an EGFR-activating mutation, is mediated in part by activation of the Src tyrosine kinase. The ability of Src to induce Fn14 gene expression was also observed in v-Src–transformed NIH 3T3 fibroblasts, so this effect may occur in most cell lines that exhibit either transient Src activation in response to growth factor exposure or persistent Src activation as a consequence of activating mutations in upstream Src regulators (e.g., receptor tyrosine kinases). It appears from our quantitative RT-PCR data that Src activation may be increasing Fn14 protein levels, at least in part, by regulating Fn14 gene transcription, but the molecular basis for this effect is currently unknown. Src targets multiple substrates (24, 25, 46–48) and many of these play key roles in intracellular signaling pathways that influence transcription factor activity (24, 25, 46). Because (i) both HCC827 and NIH 3T3/v-Src cells exhibit constitutive STAT3 Y-705 phosphorylation (Supplementary Fig. S2; refs. 44, 49), (ii) it has been reported that Fn14 is a STAT3-inducible gene (50), and (iii) a STAT3 inhibitor reduced Fn14 levels in HCC827 cells by approximately 77% (Fig. 1A), STAT3 could be involved in Src-induced Fn14 gene expression. However, this is unlikely to be the case in HCC827 cells because prior studies have shown that dasatinib treatment of these cells does not reduce STAT3 phosphorylation (activation; refs. 35, 49). Another potential intermediary signaling node that could link an increase in Src activity to an increase in Fn14 gene transcription is the NF-κB pathway. Specifically, (i) Src has been shown to modulate NF-κB signaling in various cell types (Supplementary Fig. S2; refs. 51, 52), (ii) NF-κB binding to the Fn14 promoter has been reported (14), and (iii) an NF-κB inhibitor reduced Fn14 levels in HCC827 cells by approximately 37% (Fig. 1A). Future studies...
will examine the potential roles of the STAT and NF-kB transcription factor family members in Src-mediated Fn14 expression.

Elevated Src kinase activity has been reported in a wide range of cancer types, including breast (53), ovarian (54), melanoma (55), and NSCLC (30, 31), and Fn14 is also frequently upregulated in these same cancers (11–13, 17–19). Thus, our findings suggest that the Src signaling pathway could be an important driver of Fn14 overexpression in tumor tissue. Accordingly, Fn14 downregulation could contribute to the efficacy of Src inhibitors noted in some cancer patients enrolled in clinical trials (25).

We also report here that v-Src–driven NIH 3T3 cell invasiveness through a Matrigel barrier is mediated, at least in part, by the level of Fn14 expression in these cells. Although numerous downstream effectors of Src-stimulated invasion have been identified, many of these proteins are Src substrates (e.g., FAK, CAS, and cortactin) linked to intracellular pathways that affect cell adhesion and motility (46–48). However, because Fn14 has no tyrosine residues, it cannot be an Src substrate, and therefore its proinvasive activity appears to be primarily modulated by its expression level. We have shown that elevated Fn14 levels in HEK293 cells can trigger NF-kB pathway activation, and that this can occur without ligand (TWEAK) engagement (45); therefore, Fn14 proinvasive activity may also not require TWEAK–Fn14 cell surface interaction. The molecular basis for Fn14 modulation of NIH 3T3/v-Src cell invasiveness is not known, but in glioblastoma cells there is evidence that TWEAK–Fn14 pathway–triggered invasion is mediated by the NF-kB signaling pathway (14), the SFK member Lyn (22), and the Rho GTPase family members Rac1 and Cdc42 (14, 23).

In conclusion, our novel findings showing that (i) Src, a non–receptor tyrosine kinase constitutively activated in many types of human cancer, can upregulate Fn14 gene expression, and (ii) Src-driven invasion is dependent in part on Fn14 expression, supports the notion that Fn14-targeted therapeutic agents could have broad utility for many patients with cancer, and that Fn14 inhibition could attenuate tumor cell metastatic spread.

Authors’ Contributions
Conception and design: E. Cheng, N.L. Tran, J.A. Winkles
Development of methodology: E. Cheng, T.G. Whissett
Acquisition of data (provided animals, acquired and managed patients, provided facilities, etc.): E. Cheng
Analysis and interpretation of data (e.g., statistical analysis, biostatistics, computational analysis): E. Cheng, T.G. Whissett, J.A. Winkles
Writing, review, and/or revision of the manuscript: E. Cheng, T.G. Whissett, N.L. Tran, J.A. Winkles
Administrative, technical, or material support (i.e., reporting or organizing data, constructing databases): E. Cheng
Study supervision: J.A. Winkles

Acknowledgments
The authors thank Dr. Steve Zhan (University of Maryland School of Medicine) for the NIH3T3/v-Src cell line and Rebeca Galisteo and Cheryl Armstrong for technical support.

Grant Support
This work was supported in part by NIH grants R01 CA130967 (J.A. Winkles) and R01 CA130940 (N.L. Tran). E. Cheng was supported in part by NIH training grant T32-HL007698.

The costs of publication of this article were defrayed in part by the payment of page charges. This article must therefore be hereby marked advertisement in accordance with 18 U.S.C. Section 1734 solely to indicate this fact.

Received July 23, 2014; revised November 3, 2014; accepted November 8, 2014; published OnlineFirst November 12, 2014.
