## ABOUT THE COVER

In this issue, Singh and colleagues study the recurrence of cancer mutations on potential RNA-binding protein (RBP) binding sites using whole genome sequencing data from 14 different tumor types. The study defines new alterations in non-coding regions that impact RNA processing and proposes a systematic method for aiding the interpretation of noncoding variants in cancer genomes. The cover image is based on the representation of the proportion of patient samples that show a mutated RBP binding site in each of the tumor types analyzed, coded in different colors. Colorectal tumors (cyan) and melanoma (brown) are the cancer types with the highest proportion of mutated RBP motifs. Please see the article, beginning on page 1112, for more information.
