Autophagy, Cell Viability, and Chemoresistance Are Regulated By miR-489 in Breast Cancer

Mithil Soni1,2, Yogin Patel1,2, Eleni Markoutsa3, Chunfa Jie4, Shou Liu1,2, Peisheng Xu3, and Hexin Chen1,2

Abstract

It is postulated that the complexity and heterogeneity in cancer may hinder most efforts that target a single pathway. Thus, discovery of novel therapeutic agents targeting multiple pathways, such as miRNAs, holds promise for future cancer therapy. One such miRNA, miR-489, is downregulated in a majority of breast cancer cells and several drug-resistant breast cancer cell lines, but its role and underlying mechanism for tumor suppression and drug resistance needs further investigation. The current study identifies autophagy as a novel pathway targeted by miR-489 and reports Unc-51 like autophagy activating kinase 1 (ULK1) and lysosomal protein transmembrane 4 beta (LAPTM4B) to be direct targets of miR-489. Furthermore, the data demonstrate autophagy inhibition and LAPTM4B downregulation as a major mechanism responsible for miR-489-mediated doxorubicin sensitization. Finally, miR-489 and LAPTM4B levels were inversely correlated in human tumor clinical specimens, and more importantly, miR-489 expression levels predict overall survival in patients with 8q22 amplification (the region in which LAPTM4B resides).

Implications: These findings expand the understanding of miR-489–mediated tumor suppression and chemosensitization and suggest a strategy for using miR-489 as a therapeutic sensitizer in a defined subgroup of resistant breast cancer patients.

Introduction

Despite recent advances in chemotherapy and novel treatment strategies for breast cancer, the development of broad-range treatments has been restricted due to the discrepancy in transcriptional and genomic heterogeneity of the disease, and the complexity of resistance mechanisms. Therefore, identification of a single therapeutic agent targeting multiple oncogenic and pro-survival pathways would provide a promising future cancer therapy (1, 2). Because miRNAs target multiple pathways and control gene expression of their targets, they could offer considerable therapeutic options. miRNAs are small noncoding RNAs that posttranscriptionally regulate expression of their target genes (3). Because miRNAs regulate many genes, their dysregulation have been shown to cause various pathologic conditions including cancer. Identifying such dysregulated miRNAs and their targets might provide insights for the development of novel therapy.

Previously, we have established miR-489 as a tumor suppressor miRNA in breast cancer by targeting HER2 signaling pathway (4).

Since then, several groups have demonstrated its tumor-suppressive role in many different cancers including gastric cancer, lung cancer, ovarian cancer, hepatic cancer, osteosarcoma, and bladder cancer (4–12). Remarkably, miR-489 has been reported to induce cell-cycle arrest and apoptosis, inhibit metastasis and epithelial-to-mesenchymal transition in context-dependent manner. A thorough understanding of miR-489–mediated tumor suppression in a specific cancer will be valuable in evaluating the possibility of miRNA-489–based therapy. Hence, this study was aimed to identify novel pathways and molecular targets affected by miR-489, which will lead to better understanding of miR-489–mediated tumor suppression.

Macroautophagy (referred to as autophagy now onwards) has recently received great attention in the field of cancer and chemoresistance due to its prosurvival role under stressful conditions. Autophagy is a highly conserved process by which cells capture intracellular proteins, lipids, and organelles, and deliver them to the lysosomal compartment for degradation (13). The role of autophagy in cancer remains controversial, as it exhibits tumor-suppressive and tumor-promoting activity in context and molecular subtype–dependent manner. For example, autophagy has been shown to inhibit tumor initiation and progression by protecting cells from ROS-induced DNA damage and mutagenesis. Conversely, other studies reported that autophagy protects cancer cells from metabolic stress such as starvation or hypoxia (14). Because of its cytoprotective function, it enables cancer cells to cope with cytotoxic or other stress induced by treatment. Indeed, autophagy inhibition has been shown to reverse resistance to several chemotherapeutic agents. Currently, chloroquine, an antimalarial drug, is under clinical trials for adjuvant therapy to reduce resistance via autophagy inhibition in various cancers. Many miRNAs have also been shown to sensitize cancer cells to chemotherapy by inhibiting autophagy. For example, miR-200b...
has been shown to reverse autophagy-mediated resistance to docetaxel by targeting ATG12 (15), while miR-140-5p disrupts cancer stem cell growth in colorectal cancer via autophagy inhibition (16, 17). Understanding the role of miRNA in autophagy-mediated cancer cell survival and resistance may provide detailed insight on potential miRNA-based therapies.

In this study, for the first time, we reported that miR-489 inhibits autophagy by affecting multiple genes involved in the process. We further report that miR-489 induced autophagosome accumulation is partially responsible for its cytotoxic effect. Moreover, we found that miR-489 can also sensitize breast cancer cells to doxorubicin via autophagy inhibition. From the combination of our in vitro and in vivo studies, we report that miR-489 inhibits autophagy by targeting ULK1 and LAPTM4B and sensitizes tumor cells to doxorubicin by inhibiting doxorubicin-induced cytoprotective autophagy and LAPTM4B expression.

Materials and Methods

The detailed procedures about cell lines and reagents, plasmid construction, cell culture, Western blot analysis, HCC, qRT-PCR, luciferase assay, and MTT assay are described in detail in Supplementary Experimental Procedures. All the primer sequences are listed in Supplementary Table S1.

Microarray analysis

T47D cells were seeded in 6-well culture dish, treated with 28 nmol/L scramble miRNA or miR-489 mimic for 72 hours. RNA was extracted with TRIzol reagent, followed by clean-up and DNase I treatment with QIAGEN RNeasy mini kit in accordance with the prescribed protocol provided with the kit. Quality control was performed with Agilent Bioanalyzer before performing microarray. The data were normalized using the default quantile normalization with R/bioconductor package lumi version 3.2.2. The microarray data in this manuscript is available on the GEO database (GSE99728). A subset of identified genes was listed in Supplementary Table S1.

Autophagy and cell viability assays

Breast cancer cells were transfected with 28 nmol/L scr, mimic or inh, for 68 hours, and then treated with Baflomycin A1 and LAPTM4B and sensitizes tumor cells to doxorubicin by inhibiting doxorubicin-induced cytoprotective autophagy and LAPTM4B expression.

T47D cells were transfected with 28 nmol/L scramble miRNA or miR-489 mimic for 72 hours. RNA was extracted with TRIzol reagent, followed by clean-up and DNase I treatment with QIAGEN RNeasy mini kit in accordance with the prescribed protocol provided with the kit. Quality control was performed with Agilent Bioanalyzer before performing microarray. The data were normalized using the default quantile normalization with R/bioconductor package lumi version 3.2.2. The microarray data in this manuscript is available on the GEO database (GSE99728). A subset of identified genes was validated by qPCR.

Autophagy and cell viability assays

Breast cancer cells were transfected with 28 nmol/L scr, mimic or inh, for 68 hours, and then treated with Baflomycin A1 (400 nmol/L) or DMSO for 4 hours. The levels of LC3B-I/II and SQSTM1 protein expression were assayed by Western blot analysis. MDA-MB-231 cells were transfected with scr, mimic, or inhibitor for 24 hours and then treated with 3-MA for 48 hours. Autophagic flux was then assessed by examining LC3B-II and p62 expression using Western blot analysis. MDA-MB-231 cells stably expressing mCherry-EGFP-LC3B fusion protein were transfected with scr or mimic for 48 hours and assayed for colocalization of red and green puncta using confocal microscopy.

To study effect of miR-489 on cell survival, indicated cell lines were first seeded in 96-well plate in triplicate and transfected with 28 nmol/L scr or mimic. Cell viability assay was performed using MTT reagent at 72 hours. To assess the effect of miR-489 under metabolic stress, MDA-MB-231, HCC1954, or T47D cells were seeded in a 96-well plate. Cells were transfected with scr, mimic, or inh in complete media or in low serum. Cell viability assay was performed using MTT reagent at indicated time points. Expression of cleaved caspase-3, LC3B, and p62 was analyzed using Western blot analysis. To study the role of autophagy in miR-489–induced sensitization under starvation, MDA-MB-231 cells were transfected with 9.3 nmol/L scr or mimic in complete media or low serum in presence or absence of 3-MA, siATG5, or Baflomycin A1 followed by cell viability assay using MTT reagent and Western blot analysis to examine the effect on autophagy and apoptosis. To examine the effect of miR-489 on doxorubicin-induced cytoprotective autophagy, MDA-MB-231 and HCC1954 cells were transfected with 28 nmol/L scr or mimic with or without doxorubicin. Protein was isolated 72 hours posttreatment and Western blot analysis was performed.

Chemosensitization assays

To study doxorubicin localization, cells were treated with 28 nmol/L scr or mimic for 24 hours then treated with 0.5 μmol/L doxorubicin for 48 hours followed by confocal microscopy. MDA-MB-231 cells were transfected with 9.3 nmol/L scr or mimic for 24 hours and treated with indicated concentration of doxorubicin in presence or absence of 3-MA (5 mmol/L), siATG5 (50 nmol/L), or Baflomycin A1 (50 nmol/L) for 48 hours and cell proliferation was measured by MTT assay to examine role of autophagy inhibition in miR-489–mediated doxorubicin sensitization. To assess lysosomal integrity, MDA-MB-231 cells were transfected with 28 nmol/L scr or mimic and stained with Acridine orange (1 μg/mL) for 20 minutes followed by flow cytometry and confocal microscopy.

miRNA-nanoparticles’ preparation

Liposomes were prepared as described elsewhere with slight modifications (18, 19). Briefly, cationic liposomes consisting of DOTAP and cholesterol (2:1 molar ratio) were prepared using the thin-film hydration method. The film was hydrated with nucleic free water and sonicated using probe sonicator for 15 minutes. The lipid concentration adjusted at 10 mg/mL. For miRNA-nanoparticles’ preparation, 231.4 μL of cationic liposomes and 90 μL of miRNA were mixed in final volume of 1 mL nuclease-free water. The miRNA–liposomes were allowed to stand at room temperature for 10 minutes. miRNA-nanoparticles were further decorated with sodium hyaluronate by adding 128.56 μL of 1 mg/mL sodium hyaluronate solution and kept at room temperature for another 10 minutes. The samples were condensed using Millipore centrifugal filter units.

Xenograft experiment

Six-week-old Athymic Female nude mice were purchased from Envigo. All mice were handled and maintained under supervision of veterinarian in accordance with institutional guidelines and under a University of South Carolina Institutional Animal Care and Use Committee–approved protocol. All mice were subcutaneously injected with 1 × 10⁶ MDA-MB-231 cells left flank of each mice (n = 5/group). Mouse were randomly distributed in four groups when tumor size reached 50–100 mm³. The mice were administered with control nanoparticles or miR-489–loaded nanoparticles every third day. Doxorubicin (4 mg/kg) was administered day after injection of miRNA. Tumor volumes were calculated by measuring length and width every third day. After 3 weeks, all mice were sacrificed and tumors were extracted after euthanizing all animals. Tumor volumes were calculated by modified ellipsoidal formula (1/2(l × w²)).

Clinical samples

Human breast cancer tissue samples were obtained through the South Carolina Tissue Bank with approval from the Institutional Review Board through the South Carolina Tissue Bank with approval from the Institutional Review Board.
The Review Board at the University of South Carolina. Tissue samples were randomly collected from patients who were diagnosed with invasive breast ductal carcinoma between 2003 and 2007. RNA was isolated from tumors samples and expression of miR-489, ULK1, and LAPTM4B was analyzed by qRT-PCR. Demographic and histopathology data of the patient samples are listed in Supplementary Table S2.

Statistical analyses
The statistical analyses were conducted with R and GraphPad software packages. A Student t test or ANOVA test was used for comparison of quantitative data. The clinical effect of the gene expression profiles of miR-489 in the patients with 8q22 gain/amplified tumor was evaluated using a published dataset containing 1,302 patients with breast cancer (20, 21). The median expression value was used as the cutoff to classify miR-489 expression as high or low. Recurrence-free survival was estimated using the Kaplan–Meier method and compared with log-rank test. The linear correlations between miR-489 and potential target genes expression in primary breast cancer tissues were evaluated with Pearson correlation coefficient analysis. Values of $P < 0.05$ were considered significant.

Results
Identification of novel miR-489 target genes involved in autophagy regulation in breast cancer
Recent studies revealed that miR-489 is significantly downregulated in various types of cancer. Therefore, through screening of miRNAs dysregulated by HER2, using two isogenic cell lines MCF7-Vec and MCF7-HER2, we identified miR-489 as a novel tumor-suppressive miRNA regulated by HER2 and reported double negative feedback loop between miR-489 and HER2 (4, 22). Our gene expression analysis also revealed multiple pathways affected by miR-489. We utilized target prediction tools such as miRWalk and TargetScan to identify potential miR-489 targets involved in autophagy. Consistent with our tools such as miRwalk and TargetScan to identify potential genes expression (Fig. 1B). We utilized target prediction tools to distinguish these two possibilities, we first used Baflomycin A1 immunoblot. Baflomycin A1 is a lysosomotropic agent that inhibits the V-ATPase responsible for acidification of the lysosome, and prevents fusion of autophagosomes and lysosomes (23). Comparison of LC3-II levels in the absence and presence of Baflomycin A1 allows the effects of formation and degradation to be uncoupled. As shown in Fig. 2A–C, no significant difference was detected between double treatment and lysosomotropic agent alone at 48- and 72-hour time points, suggesting that miR-489 might be blocking degradation of autophagosomes. Moreover, our finding on the clearance of cargo protein p62, another distinctive feature of autophagy, also indicated blockage of autophagosome degradation of p62 and LC3-II (Fig. 2E). To further confirm that miR-489 inhibits formation of autolysosome (AL) by blocking fusion of autophagosome and lysosome, we used common dual fluorescent LC3B reporter, which expresses an N-terminal fusion of mCherry and GFP to human LC3B (23). This reporter system enables real time monitoring of autophagic flux. Because low pH quenches GFP fluorescence, AL is seen as distinct red aggregates, while AP appears as yellow aggregates due to overlap of red and green fluorescence (Fig. 2F). If the autophagy pathway is in flux, then these yellow aggregates will be transient as APs fuse with acidic lysosomes to form ALs, in which the low pH quenches GFP fluorescence, resulting in rapid accumulation of dense red aggregates. However, blockage of autophagy at the fusion step results in accumulation of yellow puncta. Consistent with our earlier results, miR-489 mimic–transfected cells show presence of more yellow puncta compared with control, further suggesting miR-489 causes accumulation of AP by blocking fusion step (Fig. 2G and H). We also examined the effect of miR-489 restoration on starvation-induced autophagy and found substantial accumulation of p62 and LC3B-II. Interestingly, this accumulation was comparable with that of Baflomycin A1, which also blocks the fusion step (Fig. 2I). Together, these results indicate that miR-489 inhibits autophagy mainly by blocking maturation step.

Autophagy is a complex multistep process. Numerous assays have been developed to precisely decipher the effect on basal autophagy or autophagic flux. Although change in LC3B-I and II is an indicator of change in autophagy flux, it fails to provide conclusive information about autophagy activation or inhibition (23). Deposition of LC3B-II can be caused by induction of autophagosome (AP) formation or blockage of autophagosome degradation via fusion of autophagosome with lysosome (autolysosome). To distinguish these two possibilities, we first used Baflomycin A1 immunoblot. Baflomycin A1 is a lysosomotropic agent that inhibits the V-ATPase responsible for acidification of the lysosome, and prevents fusion of autophagosomes and lysosomes (23). Comparison of LC3-II levels in the absence and presence of Baflomycin A1 allows the effects of formation and degradation to be uncoupled. As shown in Fig. 2A–C, no significant difference was detected between double treatment and lysosomotropic agent alone at 48- and 72-hour time points, suggesting that miR-489 might be blocking degradation of autophagosomes. Moreover, our finding on the clearance of cargo protein p62, another distinctive feature of autophagy, also indicated blockage of autophagosome degradation (Fig. 2A–C; Supplementary Fig. S2A–S2D; refs. 23, 24). These results suggest that miR-489 inhibits autophagy by blocking formation of autophagosome and lysosome fusion (autolysosome). We then examined protein levels of some of the core autophagy genes using Western blot analysis and found significant downregulation of ULK1 upon miR-489 overexpression (Fig. 2D).

We then asked whether autophagy inhibitors that block autophagosome formation such as 3-methyladenine (3-MA) can prevent miR-489–induced autophagosome deposition. Consistent with previous observations, 3-MA indeed attenuated miR-489 induced p62 and LC3B-II deposition (Fig. 2E). To further confirm that miR-489 inhibits formation of autolysosome (AL) by blocking fusion of autophagosome and lysosome, we used common dual fluorescent LC3B reporter, which expresses an N-terminal fusion of mCherry and GFP to human LC3B (23). This reporter system enables real time monitoring of autophagic flux. Because low pH quenches GFP fluorescence, AL is seen as distinct red aggregates, while AP appears as yellow aggregates due to overlap of red and green fluorescence (Fig. 2F). If the autophagy pathway is in flux, then these yellow aggregates will be transient as APs fuse with acidic lysosomes to form ALs, in which the low pH quenches GFP fluorescence, resulting in rapid accumulation of dense red aggregates. However, blockage of autophagy at the fusion step results in accumulation of yellow puncta. Consistent with our earlier results, miR-489 mimic–transfected cells show presence of more yellow puncta compared with control, further suggesting miR-489 causes accumulation of AP by blocking fusion step (Fig. 2G and H). We also examined the effect of miR-489 restoration on starvation-induced autophagy and found substantial accumulation of p62 and LC3B-II. Interestingly, this accumulation was comparable with that of Baflomycin A1, which also blocks the fusion step (Fig. 2I). Together, these results indicate that miR-489 positive, estrogen-positive, and triple-negative breast cancer cells suggesting autophagy modulation by miR-489 is independent of breast cancer subtype. In summary, we identified autophagy as a novel pathway modulated by miR-489 expression.
inhibits autophagy mainly by blocking the fusion of APs to lysosome.

miR-489 directly targets ULK1 and LAMTM4B genes

After establishing role of miR-489 in autophagy, we sought to identify direct targets of miR-489 involved in the process. Our microarray and target prediction algorithm analyses revealed multiple genes directly involved in autophagy pathway such as ATG4A, ULK1, ATG4C, LAPTM4B, EIG121, VMA21, WIPI1, ATP6V1C1, and EI24 (Fig. 1B and C). To validate our microarray results, we performed qRT-PCR after transient transfection of mimic or scr in indicated breast cancer cell lines (Fig. 3A; Supplementary Fig. S3A and S3B). As shown in Fig. 3A, the expression of 4 of 6 genes were greatly diminished upon miR-489 restoration in multiple breast cancer cell lines. The expression of the other two genes was reduced in a cell line–dependent manner (Supplementary Fig. S1A). To further confirm, we performed Western blot analysis and found downregulation of LAPTM4B and ULK1 but not EI24 in all three cell lines (Fig. 3B). We were also interested in investigating whether knockdown of endogenous miR-489 would affect target genes expression. Indeed, miR-489 inhibitor efficiently increased the amounts of ULK1 and
We then performed 3'UTR luciferase assay to identify direct targets. Our assay revealed that ULK1 (35% reduction, \(P = 0.0184\)) and LAPTM4B (40% reduction, \(P = 0.0038\)) are direct targets of miR-489 while ATG4A might be an indirect target (Fig. 3C and D). Because ULK1 and LAPTM4B are positive regulators of autophagy, these results further suggest that miR-489 negatively regulates the autophagy.

miR-489 reduces tumor cell survival and sensitizes tumor cells under metabolic stress induced by starvation via inhibiting autophagosome degradation

Previous experiments suggest that overexpression of miR-489 may result in increased sensitivity of tumor cells to insults that induce autophagy as survival mechanism. Because starvation is a fairly common insult that requires autophagy for survival, we examined whether miR-489 overexpression can reduce tumor cell survival under starvation. We selected MDA-MB-231 cells for this study as previous study has showed that MDA-MB-231 cells are more resistant to starvation compared with other breast cancer cell lines. Study also showed that this aggressive cell line is sensitive to autophagic induction and additionally possesses the ability to proliferate following nutrient deprivation (25). Consistent with this study, we also observed that MDA-MB-231 cells were much more resistant to starvation compared with T47D and HCC1954 cells (Fig. 4A and B; Supplementary Fig. S4B and S4E). We transfected MDA-MB-231 cells with scr, mimic, or inh under complete media or starvation and performed cell survival assay at indicated time points. We found that miR-489 overexpression significantly reduced survival under starvation (\(P = 0.0001\); Fig. 4A and B). miR-489 overexpression caused more than 20% growth inhibition after 72 hours of transfection under starvation compared with nutrient-rich condition (Fig. 4C). Interestingly, this cytotoxic and cytostatic effect began as early as 24 hours under starvation, while this was not observed until 48 hours in

Data are representative of three independent experiments.

Figure 2. miR-489 inhibits autophagy mainly by blocking maturation step. A–C, Bafilomycin A1 blots after reconstituting cells with miR-489. T47D (A), MDA-MB-231 (B), and HCC1954 (C) cell lines were transfected with 28 nmol/L scr or mimic for 48 or 72 hours and p62 and LC3B-II protein expression was assayed by Western blot analysis in the presence or absence of Bafilomycin A1 (BaA1; 400 nmol/L). GAPDH was used as a loading control. D, Western blot analysis of core autophagy genes after 72 hours posttransfection. Cells were transfected with 28 nmol/L scr or mimic, for 72 hours, and then treated with Bafilomycin A1 (BaA1) for 4 hours. GAPDH was used as a loading control. E, Western blot analysis of autophagic flux after reconstitution of scr or mimic with or without autophagy inhibitor 3-MA. Cells were transfected with 28 nmol/L scr or mimic, for 24 hours, and then treated with 3-MA for 48 hours. Autophagic flux was then analyzed using Western blot analysis. GAPDH was used as a loading control. F, Schematic diagram of mCherry-EGFP-LC3B reporter. G, Confocal microscopy of autophagy maturation. MDA-MB-231 cells stably expressing mCherry-EGFP-LC3B fusion protein were transfected with 28 nmol/L scr or mimic for 4 hours and assayed for colocalization of red and green puncta using confocal microscopy. H, Quantitative analysis of red and yellow puncta in MDA-MB-231 cells at 48 hours posttransfection of scr or mimic. I, miR-489 blocks starvation induced autophagy. MDA-MB-231 cells were transfected with 28 nmol/L scr or mimic for 68 hours and treated with EBSS for the last 4 hours to induce autophagy. Bafilomycin A1 was used as a control. GAPDH was used as a loading control.

1352 Mol Cancer Res; 16(9) September 2018 Molecular Cancer Research
nutrient-rich medium. Consistent with previous observations, starvation indeed induce autophagy and miR-489 restoration showed stronger autophagy inhibition under starvation as indicated by increased accumulation of LC3-B-II and p62 in Western blot analysis (Fig. 4D). Western blot results also showed significant increase in cleaved caspase-3 upon miR-489 overexpression under starvation. We also performed similar experiment on T47D and HCC1954 cells (Supplementary Fig. S4A–S4F). Both cell lines were significantly affected under starvation. We tested whether miR-489 inhibition can protect these cells under stress induced by starvation. miR-489 inhibition marginally increased survival under starvation in HCC1954. Interestingly, this protective effect was more prominent in T47D cells (Supplementary Fig. S5C, P = 0.0017) that possesses higher endogenous miR-489 (Supplementary Fig. S5).

To examine whether cytotoxic effect of miR-489 is mediated through autophagy inhibition, we blocked autophagy at different stages using pharmacologic and RNA interference approach under nutrient-rich condition and under starvation and assessed the effect of miR-489 on autophagic flux and cell viability. We observed that blocking early stages of autophagy by 3-MA or siATG5 resulted in significant attenuation of cytotoxic effect of miR-489 (Fig. 4E and F). This rescue effect was more pronounced under starvation (Fig. 4G). In fact, 3-MA and siATG5 treatment almost completely prevented miR-489-induced apoptosis as evidenced by Western blot analysis of cleaved caspase-3 (Fig. 4H). However, autophagy blockage at later stage by Bafilomycin A1 did not rescue cells from miR-489-induced death. Rather, it mildly synergized the growth inhibition. These results suggest that increased autophagosome accumulation by miR-489 may account for its cytotoxic effect on these cells. Previous reports have shown that autophagosome accumulation confers cytotoxicity in cancer cells and blocking autophagosome synthesis by chemical inhibitor or by genetic ablation alleviates this cytotoxicity (26, 27). Starvation is known to induce autophagosome formation. Hence, restoring miR-489 under starvation resulted in

Figure 3.

miR-489 directly targets ULK1 and LAMT34B genes. A, MDA-MB-231 and T47D cell lines were transfected with 28 nmol/L scr or mimic. RNA was isolated 72 hours posttransfection and qR-PCR was performed to examine expression level of indicated genes. Data are means of three replicates ± SEM. B, Western blot analysis showing expression of potential targets upon transfection of 28 nmol/L scr, mimic, or inh in indicated cell lines. GAPDH was used as a loading control. C, A schematic representation of the target mRNA with putative miR-489–binding site in the 3′ UTR by S-fold database, where the seed region is highlighted in red. D, HEK293T cells were cotransfected with miR-489–expressing vector or empty vector and Renilla-expressing vector for 72 hours. Firefly luciferase was measured for each condition and normalized with Renilla luciferase. Normalized luciferase activity was compared with WT 3′ UTR and mutant 3′ UTR of target mRNA. Data are means of three replicates ± SEM.
pronounced increase in autophagosome accumulation. This might explain why miR-489 further sensitized cells under starvation. We also observed greater rescue from miR-489–induced death under starvation upon blocking autophagosome synthesis by 3-MA or siATG5. Further confirming the idea that miR-489–induced autophagosome accumulation is crucial for its cytotoxic effect. Previous studies have also reported similar observations where perturbation of earlier stages of autophagy attenuated the effect of autophagy inhibitors that block later stages (28).

In summary, these data suggest that miR-489–mediated autophagosome accumulation is at least partially responsible for its cytotoxic effect and it further sensitizes cancer cell death under metabolic stress induced by starvation due to further increase in autophagosome accumulation.

miR-489 acts as a therapeutic sensitizer in breast cancer cells by inhibiting doxorubicin-induced cytoprotective autophagy and directly targeting LAPTM4B

We next tested whether miR-489 could sensitize breast cancer cells to these chemotherapeutic agents. Few studies have demonstrated that miR-489 is severely downregulated in cisplatin- and doxorubicin-resistant breast cancer cell lines and tumors (12, 29). We hypothesized that restoring miR-489 can sensitize breast cancer cells to these chemotherapeutic agents. Using MTT-based cell viability assay, we found miR-489 restoration sensitized MDA-MB-231, MDA-MB-468, HCC1954, and MDA-MB-453 to cisplatin and doxorubicin (Fig. 5A; Supplementary Fig. S6A). We observed substantial sensitization of doxorubicin upon miR-489 restoration, while only a mild sensitization effect was observed with cisplatin. Remarkably, double treatment of miR-489 and doxorubicin resulted in almost complete death of MDA-MB-231 and MDA-MB-453 cells (Fig. 5A).

Doxorubicin has been previously shown to induce cytoprotective autophagy (30, 31). We examined autophagic flux upon miR-489 restoration in doxorubicin-treated MDA-MB-231 and HCC1954 cells (Fig. 5B). Consistent with previous results, we found that doxorubicin indeed increased autophagic flux. This cytoprotective autophagy was blocked by miR-489 as indicated by increased LC3B-II levels (Fig. 5B). Previous studies have demonstrated that autophagy inhibition sensitizes breast cancer cells to doxorubicin (30–32). Consistent with these results, we observed substantial sensitization of doxorubicin upon miR-489 restoration, while only a mild sensitization effect was observed with cisplatin. Remarkably, double treatment of miR-489 and doxorubicin resulted in almost complete death of MDA-MB-231 and MDA-MB-453 cells (Fig. 5A).

Doxorubicin has been previously shown to induce cytoprotective autophagy (30, 31). We examined autophagic flux upon miR-489 restoration in doxorubicin-treated MDA-MB-231 and HCC1954 cells (Fig. 5B). Consistent with previous results, we found that doxorubicin indeed increased autophagic flux. This cytoprotective autophagy was blocked by miR-489 as indicated by increased LC3B-II levels (Fig. 5B). Previous studies have demonstrated that autophagy inhibition sensitizes breast cancer cells to doxorubicin (30–32). Consistent with these results, we observed substantial sensitization of doxorubicin upon miR-489 restoration, while only a mild sensitization effect was observed with cisplatin. Remarkably, double treatment of miR-489 and doxorubicin resulted in almost complete death of MDA-MB-231 and MDA-MB-453 cells (Fig. 5A).
miR-489 and Bafilomycin A1 resulted in higher sensitization compared with siATG5. Interestingly, we observed greater sensitization with miR-489 compared with Bafilomycin A1. We then sought to examine role of autophagy in miR-489-mediated doxorubicin sensitization. Blocking autophagy at early step by siATG5 attenuated miR-489 induced drug sensitization while blocking late-stage autophagy by Bafilomycin A1 further showed mild sensitization at higher doxorubicin concentration (Fig. 5C). Furthermore, although ATG5 knockdown attenuated sensitization by miR-489, it failed to completely prevent this sensitization (see Fig. 5C). These data suggest that miR-489 may also inhibit additional pathway besides autophagy that render cells resistant to doxorubicin. Apart from inducing autophagic flux, LAPT4M4B has been shown to promote chemoresistance (36–39). Therefore, we seek to examine role of LAPT4M4B in miR-489-mediated doxorubicin sensitization.

To directly access role of LAPT4M4B, we stably overexpressed LAPT4M4B in MDA-MB-231 cell lines (Fig. 6A). As suggested by previous studies, LAPT4M4B restoration increased autophagic flux and attenuated miR-489–induced autophagy inhibition (Fig. 6C). Surprisingly, LAPT4M4B restoration increased survival by 23% (P = 0.0005) upon miR-489 overexpression (Fig. 6B). LAPT4M4B overexpression not only rescued cells from miR-489–induced apoptosis, but also increased survival by 17% (P = 0.0175) upon doxorubicin treatment and 33% (P = 0.001) upon combination treatment (Fig. 6D). To validate this result, we performed Western blot analysis to monitor apoptotic marker cleaved caspase-3 and detected significant reduction in cleaved caspase-3 in LAPT4M4B-overexpressing cell line (Fig. 6E). LAPT4M4B has been shown to sequester doxorubicin in lysosomes preventing their entry into nucleus thereby rendering it less effective (36, 37, 40, 41). We tested whether miR-489 can induce redistribution of doxorubicin in MDA-MB-231 cells and found that miR-489 indeed increased doxorubicin localization in nucleoli (Fig. 6F; Supplementary Fig. S6B). We then assessed effect of miR-489 on lysosomal integrity. We utilized Acridine orange dye which specifically stains lysosomal–endosomal organelles red. Our flow cytometry and confocal microscopy results showed reduction in red fluorescence upon miR-489 restoration (Fig. 6G and H). These results indicate that miR-489 affects lysosomal integrity and that this may be one of the mechanisms through which miR-489 sensitizes cells to doxorubicin. We also examined role of ULK1 in miR-489 induced doxorubicin sensitization. ULK1 overexpression provided mild but significant rescue from the cytotoxic and cytostatic effect of miR-489 (Supplementary Fig. S7A and S7B), but it could not rescue cells from doxorubicin (Supplementary Fig. S7C). A modest rescue was observed in double treatment, which may be due to rescue from the effect of miR-489. Collectively, these results indicate that miR-489 sensitizes MDA-MB-231 cells to doxorubicin via inhibiting doxorubicin induced cytoprotective autophagy and through doxorubicin redistribution induced by LAPT4M4B downregulation.

miR-489 sensitizes breast cancer cells to chemotherapy in vitro

Given the in vitro findings and clinical significance, we tested whether miR-489 could sensitize tumors to doxorubicin in vivo. To explore the possibility of using miR-489 for therapy, we developed a nanoparticle delivery system to deliver miR-489 into tumor cells (4). In-vitro treatment with miR-489 packaged...
nanoparticle inhibited target genes (Supplementary Fig. S8A), indicating that nanoparticles can effectively deliver miR-489 into tumor cells. Our qRT-PCR analysis on tumor samples confirmed successful delivery of miR-489 and downregulation of ULK1 and LAPTM4B mRNA (Supplementary Fig. S8B–S8D). Consistent with our in vitro data, miR-489 indeed sensitized cells to doxorubicin in vivo (Fig. 7A). Tumor growth in mice treated with doxorubicin alone was moderately reduced compared with control, while mice treated with miR-489 exhibited a significant reduction in tumor growth compared with control (P = 0.0441) and doxorubicin (P = 0.0284). Tumor growth in mice treated with the combination of doxorubicin and miR-489 was significantly reduced compared with control (by more than 75%; P = 0.0066), monotherapy with doxorubicin (by more than 40%; P < 0.0001), or miR-489 alone (by more than 20%; P = 0.0326; Fig. 7A). Our IHC data revealed reduced cytoplasmic staining of LAPTM4B and significant reduction in number of Ki67-positive cells in combination treatment when compared with the control tumors (Fig. 7B and C, P < 0.0001). Western blot analysis of tumor samples indicated autophagy inhibition and downregulation of ULK1 and LAPTM4B (Fig. 7D). Together, these data demonstrated that miR-489 delivered through nanoparticles

Figure 6. miR-489 sensitizes breast cancer cells to doxorubicin partly by targeting LAPTM4B. A, Western blot analysis indicating stable over expressing LAPTM4B. GAPDH was used as a loading control for Western blot analysis. B and C, MDA-MB-231 cells stably expressing LAPTM4B were transfected with 28 nmol/L scr or mimic. Cell viability assay (B) and Western blot analysis (C) was performed 72 hours posttransfection to examine autophagic flux and apoptosis. D and E, MDA-MB-231 cells stably expressing LAPTM4B were transfected with 28 nmol/L scr or mimic with or without doxorubicin followed by cell viability assay (D) and Western blot analysis (E). F, Microscopy analysis of subcellular localization of doxorubicin. Confocal microscopy was performed 72 hours after MDA-MB-231 cells were treated with 28 nmol/L scr or mimic with doxorubicin. Data are means of three replicates ± SEM. Data are representative of three independent experiments. G, MDA-MB-231 cells were transfected with 28 nmol/L scr or mimic and stained with Acridine orange (1 mg/mL) for 20 minutes and flow cytometry was performed to examine lysosomal integrity. H, Confocal microscopy of MDA-MB-231 cells after transfection with scr or mimic and staining with Acridine orange (1 mg/mL) for 20 minutes. Data are representative of three independent experiments.
miR-489 increases AP as shown by more yellow puncta in 8q22-amplified patients. In 8q22-amplified patients, miR-489 upregulates autophagy-related genes, including ULK1, LAPTM4B, and other autophagy genes. This upregulation of autophagy genes is supported by the enhanced expression of LC3B and p62, which are important autophagic markers. The upregulation of LC3B and p62 in 8q22-amplified patients suggests the activation of autophagy in response to the increased miR-489 levels. The increased expression of LC3B and p62 indicates that miR-489 promotes autophagy in breast cancer cells.

**Discussion**

In this study, we show that miR-489 inhibits autophagy in multiple subtypes of breast cancer cell line. Restoration of miR-489 reduces viability of MDA-MB-231 under stress induced by starvation. Finally, we show miR-489 can sensitize breast cancer cell lines to doxorubicin in vitro and in vivo. miR-489 imparts these phenotypic effects partly by directly targeting LAPTM4B and ULK1.

Our gene expression analysis reveals downregulation of many autophagy-related genes upon miR-489 reconstitution. Although, we observe that miR-489 affects multiple genes involved at different stages of autophagy, we conclude that miR-489 restoration is mainly associated with defective maturation that leads to AP accumulation. The defect at this fusion step caused by miR-489 blockage at maturation step prevents this degradation and results in simultaneous accumulation of both proteins. Second, no further significant accumulation of LC3B-II and cargo protein p62. Upon completion of the autophagic process, p62 and LC3B-II are degraded via fusion with lysosome. However, blockage at maturation step prevents this degradation and results in simultaneous accumulation of both proteins. Second, no further significant accumulation of LC3B-II was observed in 8q22 gain/amplified tumors. Patient survival was estimated using the Kaplan-Meier method and compared with log-rank tests. The y-axis represents the probability of overall survival. *P < 0.05; **P < 0.01; ***P < 0.001.

**miR-489 Regulates Autophagy in Breast Cancer Cells**

Nanoparticle-delivered miR-489 inhibits tumor growth and sensitizes cells against doxorubicin in vivo. A, miR-489 inhibits tumor growth and sensitized cells against doxorubicin in xenograft animals. After the tumors were palpable, the animals were randomly assigned into four groups (n = 5 per group). All animals were injected with miR-489 or control encapsulated in nanoparticle every third day. The treatment starting day was referred to as “Day zero” in the figure. B, IHC analysis revealed reduced expression of LAPTM4B and Ki67 in tumors treated with miR-489 encapsulated nanoparticles. C, Quantification of Ki-67-positive cells in tumors of all four groups. D, Western blot analysis of tumors revealed down regulation of ULK1, LAPTM4B, and autophagy inhibition by miR-489. GAPDH was used as a loading control. E, miR-489 and LAPTM4B expression was measured in breast tissues form breast cancer patients (n = 14) using qPCR. F, Correlation of miR-489 and its potential target gene expression in primary breast cancers. The linear dependence between miR489 and its potential target genes was evaluated by Pearson analysis of a published breast cancer dataset (38). G, miR-489 expression predict overall survival of breast cancer patients with 8q22 gain/amplified tumors. Patient survival was estimated using the Kaplan-Meier method and compared with log-rank tests. The y-axis represents the probability of overall survival. *P < 0.05; **P < 0.01; ***P < 0.001.

miR-489 and LAPTM4B expression are inversely correlated in breast cancer tissues

To further define the clinical relevance of our findings, we examined miR-489 and LAPTM4B expression in breast tissues from breast cancer patients (n = 14). We found significant inverse correlation between expression of miR-489 and LAPTM4B (Fig. 7E). Similarly, in silico analysis on primary tumors revealed a strong inverse correlation between miR-489 and LAPTM4B expression with a P value of 0.0000413 (Fig. 7F). In the clinical dataset, although statistically not significant, we found patients with higher miR-489 possess lower ULK1 expression (Supplementary Fig. S9A).

However, we do not observe inverse correlation between miR-489 and ULK1 in breast tissues from patients with breast cancer (n = 19; Supplementary Fig. S9B).

Considerable clinical evidences suggest that LAPTM4B overexpression promotes autophagy and chemoresistance (36, 37). One study shows that this overexpression is through amplification of the gene. The gene resides on 8q22 region, which is amplified in 20% of breast cancer patients (36). Therefore, we evaluated the clinical effect of the gene expression profiles of miR-489 in the patients with 8q22 gain/amplified tumor using a published dataset containing 1,302 breast cancer patients (20, 21). Intriguingly, we found that 8q22 amplified patients with high miR-489 have a significantly better survival as compared with low miR-489 (P = 0.0005; Fig. 7H). These results indicate potential application of miR-489 as prognostic biomarker in 8q22-amplified breast cancers.

**Discussion**

In this study, we show that miR-489 inhibits autophagy in multiple subtypes of breast cancer cell line. Restoration of miR-489 reduces viability of MDA-MB-231 under stress induced by starvation. The y-axis represents the probability of overall survival. *P < 0.05; **P < 0.01; ***P < 0.001.
Monoclonally associated with decreased autophagic flux due to reduced autophagosome formation. In contrast to this notion, we observed accumulation of AP. However, it is worth to note that while ULK1 is involved in the initiation stage of the autophagy, it is not essential for activation of the LC3 conjugation machinery. Studies show that ULK1 and ULK2 (homolog of ULK1) possess redundant roles in autophagy (42, 43) and indeed, it takes a double knockout of Ulk1 and Ulk2 to completely block amino acid starvation-induced autophagy in mouse embryonic fibroblasts (44). This could be one of the reason why, despite ULK1 downregulation by miR-489, collective effect is observed at maturation stage. LAPT4M4B is a lysosomal transmembrane protein that has been shown to affect maturation of autophagosomes. Studies show that knockdown of LAPT4M4B results lysosomal membrane permeabilization (45) and increases lysosomal pH1, which inhibits lysosome and autophagosome fusion (40). This results in accumulation of autophagosome with simultaneous deposition of LC3B-II and p62. Together, these results indicate that miR-489 inhibits autophagy mainly through inhibiting autophagosome maturation.

Autophagy has a contentious role in tumorigenesis. Loss of autophagy promotes oxidative stress, activation of the DNA damage response and genome instability that are known cause of cancer initiation and progression (46). However, autophagy has also been seen to promote tumor cell survival. Being a prosurvival mechanism, it allows cell survival under stressful conditions such as starvation and hypoxia. Because of excessive prosurvival mechanism, it allows cell survival under stressful conditions such as starvation and hypoxia. Because of excessive proliferation rate, these conditions are fairly common among tumors (47). Autophagy, in such established tumors, promotes survival of cancer cells and inhibition of autophagy leads to tumor growth inhibition. Furthermore, genotoxic stress induced by various chemotherapeutic agents also induces cytotoxic autophagy. Several studies have reported that inhibiting autophagy in such cases leads to tumor growth inhibition and chemosensitization. However, impact of autophagy inhibition on tumor cell survival and chemosensitization depends on at which stage autophagy in blocked. Studies show that blocking autophagy at later stage have pronounced cytotoxic effect and sensitization. In fact, few studies suggested that blocking early-stage autophagy might promote survival and attenuate effect of chemotherapeutic agent. One such report explained that this contrasting response of autophagy inhibition at different stages is because this toxic effect is attributed to autophagosome accumulation (26). Because inhibition of early stage of autophagy inhibits autophagosome synthesis, it alleviates cytotoxicity induced by autophagosome accumulation. Consistent with this result, blocking early stage of autophagy by 3-MA and siATG5 blunted miR-489–induced cell death. These results suggest application of miR-489 in tumors with increased autophagic flux or autophagy dependency. Few studies demonstrate higher basal autophagic flux and increased dependency of TNBC cells on autophagy for their survival (48). Intriguingly, we observed significant cytotoxic effect of miR-489 in TNBC cells compared with cell lines of other breast cancer subtypes. TNBC cell line MDA-MB-231 is sensitive to autophagic induction and additionally possesses the ability to proliferate following nutrient deprivation (25). In this study, we also observed MDA-MB-231 cells are more resistant to starvation compared with estrogen-positive T47D cell line and HER2-positive HCC1954 cell line. miR-489 under these conditions can provide useful therapeutic approach to target such resistant and aggressive tumor cells. Interestingly, several groups including us have shown that miR-489 is significantly downregulated in TNBC patients and cell lines, which might contribute to increased autophagic flux observed in this subtype (4, 29). All these evidences suggest a notion that loss of miR-489 in this subtype might play an important role for their survival. It will be interesting to explore whether miR-489 mediated severe cytotoxic effect on these cells is specifically due to their increased sensitivity to autophagy inhibition or if miR-489 shuts down other protumorigenic pathways aberrantly overexpressed in this subtype.

miR-489 has long been reported in drug resistance (12, 29, 49, 50). Various drug-resistant cell lines, such doxorubicin-resistant cell line, tamoxifen-resistant cell line, and cisplatin-resistant cell line, display significantly reduced miR-489 expression. A study showed that MCF7/ADR cells have significantly higher basal autophagy level and inhibition of autophagy leads to sensitization of these resistant cells to doxorubicin (51). Interestingly, restoration of miR-489 leads to significant sensitization toward doxorubicin. A study reported that miR-489 sensitizes MCF7/ADR cells by inhibiting epithelial-to-mesenchymal transition (52) through SMAD3 downregulation (50). Several studies showed cells that underwent EMT require autophagy activation to survive during the metastatic spreading (53). Furthermore TGFβ, a master regulator of SMAD3 and EMT, has also been shown to induce autophagy and knockdown of SMAD3 attenuates TGFβ-induced autophagy (54). However, on the other side, autophagy has also been shown to contrast the activation of the EMT mainly by selectively destabilizing crucial mediators of this process (53). It will be very interesting to explore cross-talk between miR-489, autophagy, and EMT to gain better understanding of miR-489’s role as therapeutic sensitizer.

Restoration of miR-489 in some of these cell lines showed sensitization to specific chemotherapeutic agent (12, 29, 49, 50). Many mechanisms exist for drug resistance. The fact that miR-489 sensitizes cells to multiple chemotherapeutic agents indicates that miR-489 regulates several pathways involved in drug resistance. One study showed miR-489 can sensitize doxorubicin-resistant cell line via targeting SPIN1–PI3K–Akt pathway (29). In this study, we establish miR-489–LAPT4M4B-Autophagy pathway as an additional mechanism involved in doxorubicin resistance. Our findings are consistent with previous studies that show role of LAPT4M4B in increased autophagy and anthracycline resistance. Our clinical analysis found patient with 8q22 amplification, who have higher miR-489 expression, have better survival (P = 0.0005) than patients with lower miR-489 expression. These data indicate potential clinical significance of miR-489 in 8q22-amplified patients, where it can mitigate effects of amplified LAPT4M4B and sensitizes patients to doxorubicin. Together, these data suggest a possible application of using miR-489 as a potential biomarker or therapeutic sensitizer in a defined subgroup of patients with resistant breast cancer.
