ABOUT THE COVER

Internalization of activated epidermal growth factor receptor (EGFR) via early endosomes plays a key role in mediating EGFR signaling and activity. The cover depicts a three-dimensional rendering of EGFR-containing endosomes as calculated from the average immunofluorescence intensity of EGFR-phospho 1068. The authors found that non-cancerous MCF10A cells exhibited a rapid increase in endosome size and phospho-1068 EGFR, which returned quickly to baseline levels. By contrast, cancerous MDA-MB-231 cells exhibited a slightly delayed increase in these metrics and larger endosomes overall, which persisted over a longer duration and correlated with sustained EGFR signaling. Concordantly, modulation of endosome size via ablation or over-expression of Rab4A was shown to harbor implications for the strength and duration of EGFR activation in breast cancer cells.
